

ABSTRACT

A system for business processes performs one or more complex business processing functions. In one implementation, the system includes a user interface to collect data from a user and an intermediate layer to collect data from the user interface. The system also
5 includes business logic that can process the data collected from the intermediate layer. The intermediate layer can be interposed between the user interface and the business logic and configured to rearrange data collected by the user interface into a format that is optimized for processing by the business logic.
